

React Js

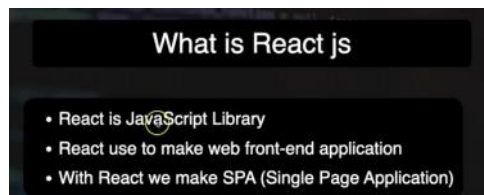

Wednesday, December 3, 2025 10:46 PM

Install node js
Visual studio
Npm create vite
Npm install
Npm run dev

[React JS 19 Full Course in Hindi | Learn React from Scratch \(2025\) in One Video](#)

<https://vite.dev/guide/>
<https://react.dev/learn>

Section 1:- Introduction to React JS

React js is not framework while angular is framework

Single page application : when we go from one page to another application will not refresh

Section 2:- react js setup with vite tool

Note :

Once we install node js , npm also will get installed

Using npm we can run vite command

Vite will help to create react js project

Vite is a **next-generation build tool** that is often used when creating React applications. It is designed to be **faster, lighter, and more efficient** than older tools like **Create React App (CRA)** or Webpack.

🚀 What Vite Does in React

When you create a React app using Vite, it provides:

1. **Super-fast development server**
 - Vite uses **native ES modules (ESM)** in the browser.
 - It starts the dev server almost **instantly**, even for large projects.
2. **Lightning-fast Hot Module Replacement (HMR)**
 - When you edit files, Vite updates the browser **immediately** without refreshing the page.
3. **Modern build process**
 - Uses **Rollup** under the hood for optimized production builds.
 - Produces smaller, faster, and more efficient bundles.

LTS : long term support

```
C:\Users\Admin>node -v
v24.11.1

C:\Users\Admin>npm -v
11.6.2
```

Vite is use to set up react js (use vite or parcel)

Frontend development tool

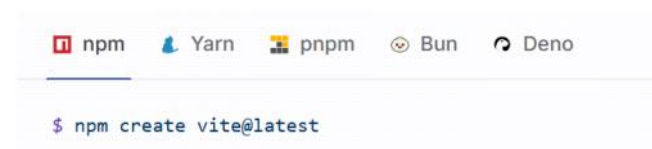

<https://vite.dev/guide/>

Manual Installation

In your project, you can install the `vite` CLI using:

Scaffolding Your First Vite Project

SWC: speedy web compiler

Command : to create project

Npm create vite

```
Shortcuts
press r + enter to restart the server
press u + enter to show server url
press o + enter to open in browser
press c + enter to clear console
press q + enter to quit

uuu
u

Local: http://localhost:5173/
Network: use --host to expose
```

✓ What npm install Does

When you run:

npm install

it:

1. Installs all dependencies listed in package.json

Example fields:

```
"dependencies": {
  "react": "^18.2.0",
  "react-dom": "^18.2.0"
},
"devDependencies": {
  "vite": "^5.0.0"
}
```

npm install downloads all these packages.

2. Creates the node_modules folder

This folder contains all installed packages + their internal dependencies (thousands of small files).

3. Creates or updates package-lock.json

This file ensures all systems get the exact same versions of packages.

4. Rebuilds dependencies if needed

Sometimes npm needs to compile native modules.

 **In simple words:**

npm install downloads all the libraries your project needs so your app can run.

Step to create project

Npm create vite

Npm install (will install all dependencies and install node modules)

Npm run dev

This is latest -----imp

npm create vite@latest my-react-app -- --template react

Go inside my-react-app :- npm install

Npm run dev

<http://localhost:5173/>

=====

Section 3:- first code or hello world in react js

Ctrl+shift+d

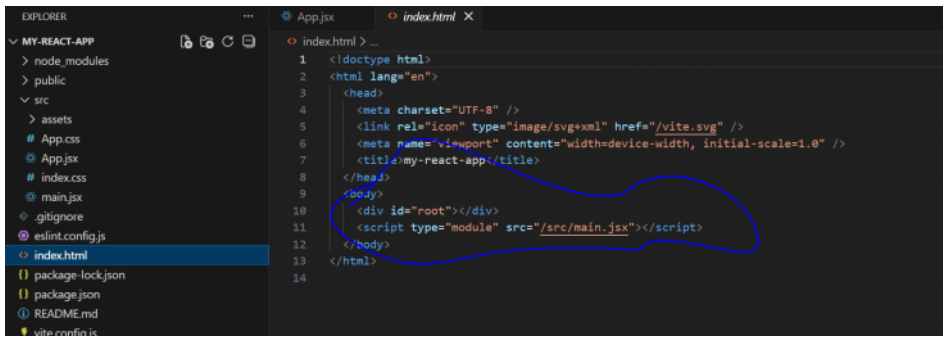

It will ask to create launch.json for debug

```
{
  "version": "0.2.0",
  "configurations": [
    {
      "name": "Debug React + Vite",
      "type": "pwa-chrome",
      "request": "launch",
      "url": "http://localhost:5173",
      "webRoot": "${workspaceFolder}\\src",
      "breakOnLoad": true
    }
  ]
}
```

Imp :

Step 1 :-Index.html execute or load first in project

All the code will inside div root

The image shows the VS Code Explorer on the left with the file structure of a project named 'MY-REACT-APP'. The 'index.html' file is selected and its content is displayed in the main editor. The HTML structure includes a head section with meta tags and a body section containing a root div and a script tag for 'main.jsx'.

```

1 <!doctype html>
2 <html lang="en">
3 <head>
4   <meta charset="UTF-8" />
5   <link rel="icon" type="image/svg+xml" href="/vite.svg" />
6   <meta name="viewport" content="width=device-width, initial-scale=1.0" />
7   <title>my-react-app</title>
8 </head>
9 <body>
10  <div id="root"></div>
11  <script type="module" src="/src/main.jsx"></script>
12 </body>
13 </html>

```

all code will be under div root

localhost:5173

Vite + React

The image shows the Chrome DevTools Elements panel. The DOM tree on the left highlights the root div element. The Styles panel on the right shows the default styles for the root element.

```

<div id="root"></div>
<script type="module" src="/src/main.jsx?l=1764290216940"></script>

```

Step 2:- Script tag will load main.jsx file

The image shows the VS Code Explorer on the left with the file structure of a project named 'MY-REACT-APP'. The 'main.jsx' file is selected and its content is displayed in the main editor. The JavaScript code imports 'StrictMode' and 'createRoot' from 'react' and 'react-dom/client', and then renders the 'App' component into the root div.

```

1 import { StrictMode } from 'react'
2 import { createRoot } from 'react-dom/client'
3 import './index.css'
4 import App from './App.jsx'
5
6 createRoot(document.getElementById('root')).render(
7   <StrictMode>
8     <App />
9   </StrictMode>,
10 )
11

```

Using document.getElementById('root') ----- it will search root in index.html whatever App.jsx code is there That will include in root div and display

Main.jsx :- include app.jsx file

Note :

app.jsx will be called as component

In main.jsx :- ./index.css which represent css is applied

For understanding

1. What is JSX?

JSX stands for **JavaScript XML**. It's a syntax extension for JavaScript that lets you write HTML-like code inside JavaScript.

Example:

```

function App() {
  return (

```

```

<div>
  <h1>Hello, React!</h1>
</div>
);
}

```

Here:

- <div> and <h1> look like HTML.
- But this code is actually JavaScript under the hood.
- React transforms JSX into React.createElement() calls when building.

2. Why .jsx instead of .js?

- **Clarity:** .jsx tells tools and developers that the file contains JSX syntax.
- **Tooling:** Some editors, linters, and compilers treat .jsx files differently, enabling syntax highlighting, autocomplete, and error checking for JSX.
- **Optional:** Technically, React can handle JSX inside .js files too, but using .jsx is considered a best practice.

3. How it works with Vite or React

- Vite (or Babel, CRA, Next.js, etc.) **automatically compiles JSX** into regular JavaScript that browsers understand.
- Example compiled code from JSX:

```

// JSX
const element = <h1>Hello</h1>;
// Compiled JS
const element = React.createElement('h1', null, 'Hello');

```

✓ In short:

- .jsx = JavaScript + HTML-like JSX code
- Helps **React developers** write components in a clean, readable way
- Compiled into standard JavaScript by build tools like **Vite**

5. Copilot Shortcuts

Action Shortcut (Windows)

Trigger suggestions	Ctrl+Enter
Accept suggestion	Tab
Show alternative	Alt+[/ Alt+]
Open Copilot panel	Ctrl+Shift+P → “Copilot: Open Panel”

1. What export does

- export is used to make a variable, function, or class available to **other modules/files**.
- Without export, the code is private to that file.

2. What default means

- default means this is the **main thing exported from this file**.
- When another file imports this module, it can import it **without using curly braces**.

3. Example in React

Suppose you have a React component App.js:

```

function App() {
  return (
    <div>
      <h1>Hello, World!</h1>
    </div>
  );
}

```

// Export the component as the default export
export default App;

Now, in another file, you can import it like this:

```

import App from './App'; // No curly braces needed
function Main() {
  return <App />;
}

```

- If it were a **named export** (export { App };), you would need curly braces:

```
import { App } from './App';
```

Option A: Temporarily Disable

- Press **Ctrl+Shift+P** (Windows) to open the Command Palette.
- Type **"Copilot: Disable"**.
- Select:
 - **"GitHub Copilot: Disable for this workspace"** → stops suggestions only in the current project.
 - **"GitHub Copilot: Disable globally"** → stops suggestions in all projects.

=====

Note :

Html tag start with small element and react component should be start with cap then only
It understand this is react tag

Always create component with capital letter (function)

If we are using multiple h1 we need to wrap it in div tag

```
src > App.jsx > App
1  function App() {
2    return (
3      <div>
4        <h1>hello react</h1>
5        <h1>welcome to React</h1>
6      </div>
7    )
8  }
9  export default App;
```

JSX : javascript xml

Library flow we can decide and framework is having own flow

=====

Section 4:- Use and Learn React without installation
